A varicocele is a benign enlargement of the pampiniform plexus of veins around the testis. The pampiniform plexus contains veins that carry blood from the testis to the rest of the body. It extends from the cremasteric artery to the spermatic vein and forms part of the testicular vascular system. Varicocele occurs when a pampiniform vein becomes twisted and is trapped within the pampiniform plexus, creating an abnormal blood flow from the testes. It is more common in men who are overweight. . (www.varicocele-relief-guide.com/varicocele-treatment-without-surgery) The Varicocele (VAR-kie-see-LEE-see): A "Practical" Misconception. The Varicocele (Varicochea Varicocele) is usually a one and half to two centimeter diameter thick-walled vein that is normally positioned in the spermatic cord, just before the testicular artery, but that can also be found in the retroperitoneum and the adrenal gland. A large varicocele is a treatable cause of pain in men. It is an abnormal dilated lymphatic channel that is found in the scrotum and surrounds the spermatic cord. In the USA, varicoceles occur in about 10 percent of the male population. In India and Pakistan, about 20 percent of males have them. Peroxidase-labeled secondary antibody used as a label of the redox-sensitive fluorescent probe Alexa 594 maleimide. The FRET-based redox-sensitive fluorescent probe, 6-carboxy-2',7'-dichlorodihydrofluorescein (DCFH), was used to monitor intracellular reactive oxygen species (ROS). It was conjugated with the maleimide-labeled secondary antibody used for immunostaining and then it was studied as to how the labeling of the secondary antibody affected its ROS detection. The labeling efficiency of the antibody (maleimide-labeled or non-labeled) used as a secondary antibody in immunostaining was also examined. The resulting labeled antibody had good labeling efficiency of the maleimide residue, and it had no apparent effect on the immunostaining. The labeling of the antibody affected its ROS detection. In the presence of ROS, the oxidized DCFH molecule had a reduced fluorescence because of the energy transfer from the DCFH molecules to the antibody. Thus, the oxidized DCFH molecule was more efficiently detected than the reduced DCFH molecule. However, the immunostaining showed no significant change in its detection sensitivity even in
